

NSE Near-52W-Low Stock Screener

AICA Level 2 Certificate Course – Capstone Project

Executive Summary

A desktop-based NSE equity screening application that retrieves NSE data, applies six transparent screening tests and produces an auditable Excel report.

Problem Statement

The project automates a repeatable equity-screening process covering 52-week levels, short-term returns, volume and 20-day moving-average proximity.

AI Usage & Prompt Engineering

ChatGPT was used for project ideation, requirements structuring, prompt engineering, Python code generation/refinement, debugging and documentation. The final executable is deterministic and does not call a generative-AI API or execute a machine-learning prediction model.

Human Contribution & Validation

The participant defined and reviewed the financial methodology, reviewed/adapted AI-generated code, tested the application and validated the workflow.

Prompt Documentation

Representative development prompts are supplied separately. They are not claimed to be verbatim historical prompts because a complete transcript is not part of the supplied project files.

Responsible AI

The executable is a transparent rule-based screening tool, not an autonomous investment decision-maker or a guarantee of future performance.
