

The process and technology used by lovable to prepare the project

This project was built as a web app using a modern React framework called TanStack Start, which handles both the visible page and the server-side logic in one codebase. The styling uses Tailwind CSS with a custom dark emerald/glass design, and the form components come from shadcn/ui.

For the AI interviewer, the app calls the Lovable AI Gateway from the server, so your prompts go to a secure backend rather than exposing any API key in the browser. It uses Google Gemini 3.7 Flash for adaptive interview questions, with a fallback if a web-search grounding tool isn't available.

Voice input is handled by recording your microphone in the browser, encoding the audio as WAV, and sending it to a server endpoint that transcribes it using OpenAI's GPT-4o-mini-transcribe model — again, through the same secure gateway. Voice output uses your browser's built-in text-to-speech. The camera preview uses the standard browser webcam API and stays entirely on your device; no video is uploaded anywhere.

All of this means you can open the app, pick a job family and role, paste a job description, and start practising immediately without signing up or entering any API key.
